## Review Article

Volume 1 Issue 1

**Received Date:** May 23, 2017

**Published Date:** June 15, 2017

**DOI:** 10.23880/jenr-16000105

## Abstract

A review is given regarding the medicinal plant *Calotropis procera* (Aiton) W.T a member of the family (Asclepiadaceae) commonly known as Giant Milk weed. It demonstrated that *Calotropis* is a perennial xerophytic woody shrub that has a great capacity to inhabit abandoned lands, it tolerated poor soils with limited nutrition and moisture, known to establish an intensive root system as a drought resistance mechanism. It exhibited allelopathic properties and phytoremediation, considered invasive in many habitats.

*C. procera* is widespread in tropical and subtropical regions of the globe, in Egypt it's distributed through several phytogeographic regions with different edaphic properties, consequently, it showed great polymorphism and wide variety in metabolites in accordance to different environments. The seeds possess a unique silk formation that aided in dispersal through wind, water or any moving substance.

Environmental conditions specially precipitation rates, was found to control the invasive behavior of the species since it showed no invasive attribute in arid environments where it's originally found such as Egypt or Saudi Arabia, on the contrary, Australia for instance knew *C. procera* as an invasive naturalized plant.

A great benefit could be taken from *Calotropis procera* on many levels, as on one hand it is known traditionally, in folk medicine to have purgative and anthelmintic properties and used in treating leprosy, ulcers, tumors and piles as well as purgative, anticoagulant, and anticancer, moreover, the plant's latex has been known for cardiac glycoside content and contains compounds with pesticide properties, while on the other hand, its biomass proved a tendency to be a good source of renewable energy and hydrocarbon. Finally, *Calotropis procera* populations have an immense ecologic role being habitat for several organisms, displaying phytoremedy properties in contaminated soils and its ability to rehabilitate deserted land bringing back life once again.

**Keywords:** Renewable energy; Bioremediation; Allelopathy; Pesticide; Invasives; Cardiac glycosides; Uscharin

## Introduction

Medicinal plants provide a major cultural and biological weight to humanity. They serve as food source, flavoring spices, means of remediation, energy source and national income [1]. The use of medicinal plants in drug manufacture has become a global trend in the last two decades [2]. Farnsworth and Soejarto; Schippmann, et al. [3-4] have estimated the plants used medicinally worldwide of more than 53000 species.

The plant family Asclepiadaceae includes more than 2,000 species classified under 280 genera are distributed worldwide in the tropical and sub-tropical regions [5]. As a family member, *Calotropis procera* has captured the attention since on one hand, it has a great value as a medicinal plant with notable importance in folk medicine (Boulos) [6], its cardiac glycoside content and the ability to act as a pesticide [7-10]. On the other hand, researches have discussed its potential to be source of renewable energy and hydrocarbon [11,12].

The plant is a perennial xerophytic woody shrub which is able to thrive in harsh conditions of heat, drought and poor soils [13,14]. It's characterized with a unique seed structure that counts primarily for its great dispersal capability. *C. procera* is widespread in tropical and subtropical regions of the globe, in Egypt its distributed through several phytogeographic regions, and is spreading further to inhabit new ecosystems [15,16].

*Calotropis procera* has significant morphological plasticity enables it to thrive harsh conditions of drought, salinity and waterlogging [17,18]. As well as wide range of temperatures and urban stress . It reproduces by seeds and vegetative propagation as well [19,14].

The significant dispersal of *Calotropis procera*, along with its high adaptability to severe environments, has driven researchers to consider its invading abilities, it even suffers widespread cutting in several regions as an invasion control strategy [20]. However, the numerous benefits and outcomes from using the plant in industrial and therapeutic aspects could possibly overcome the invasion concerns. In Egypt, even though being widespread, *C. procera* populations didn't exhibit invasive behavior yet. This review aims at assessing the *Calotropis procera* (Aiton) population in Egypt, discussing its distribution, population dynamics and dispersal behavior with respect to its ecological role and potential economic importance.

## Geographic Distribution

*Calotropis procera* (Aiton) W.T a member of the family (Asclepiadaceae), *Asclepias procera* Aiton is the most common synonym for it (Boulos) [21]. *Calotropis procera* is widely distributed around the globe and hence it has several common names, it is known in Arabic as Ushar or Oshar [22,23]. While in English it's Giant milk weed, Sodom apple, calotrope, French cotton, in French it's Bois canon or Arbre de soie, it's Algodón de seda in Spanish [24], cabbage tree, rubber bush and rubber tree [14].

It is native to tropical and subtropical Africa, (Somalia, Egypt, Libya, south Algeria, Morocco, Mauritania and Senegal), Madagascar, Asia (India, Pakistan, Afghanistan, Iran, Arabia and Jordan), Southern Asia, and Indochina to Malaysia [25,13]. The plant has been naturalized in Australia, Central and South America, the Caribbean islands, Indonesia, and many Pacific islands [13], (Figure 1).

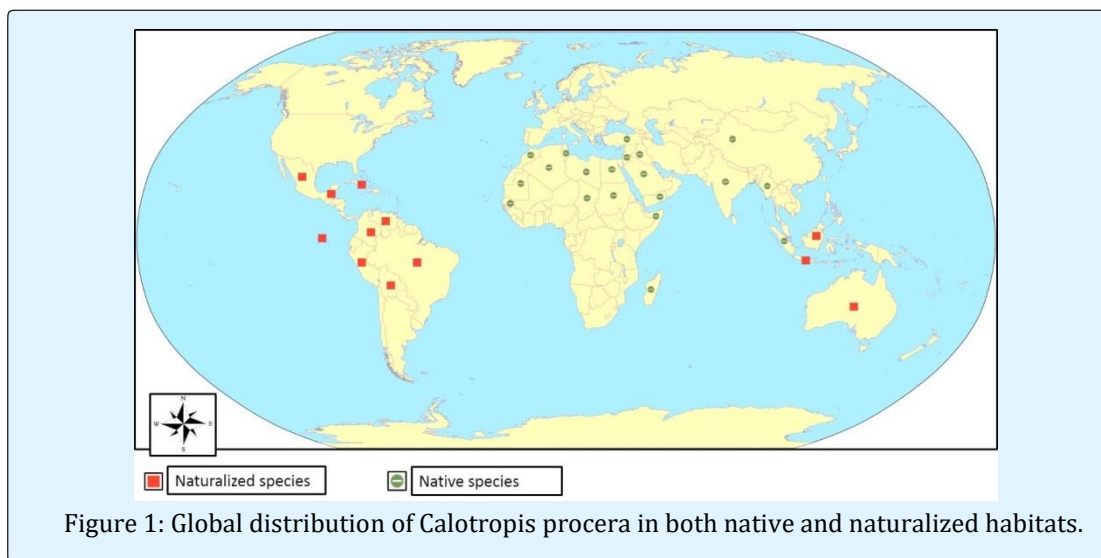

Figure 1: Global distribution of *Calotropis procera* in both native and naturalized habitats.

In Egypt, urban areas of Helwan, South Cairo Province [26], Aswan, Nile river islands and its sandy bank, New Valley (El-Kharga oases, Cairo-Suez road from, the Galala desert, the northern province of the desert east of the Nile, Wady Feran, (Saint Catherine mountain area), Nuweibaa from, Aqaba Gulf sector of the Red Sea coastal plains; and Arish, the Mediterranean coastal land [15], El Maghara, from Northern anticlines of Sinai; Shalateen, from Gebel Elba district at the South-East Eastern Desert on the Red Sea, (Figure 2).

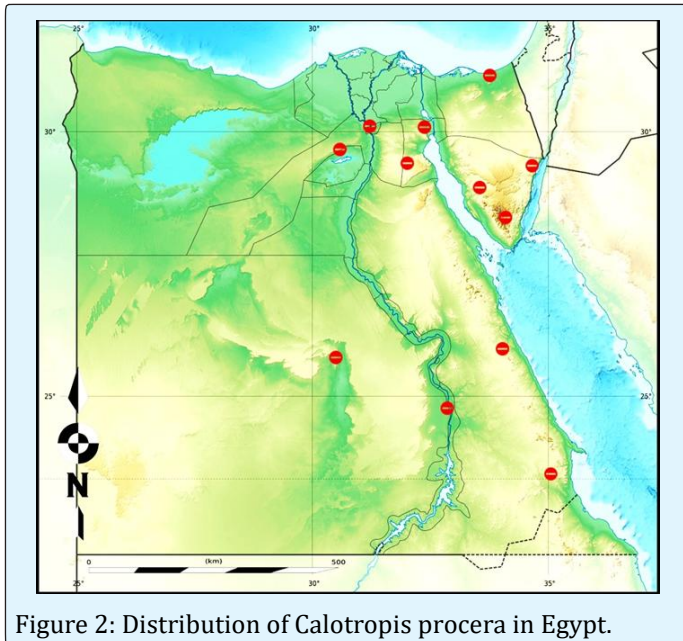

Figure 2: Distribution of *Calotropis procera* in Egypt.

### Morphology

*Calotropis procera* is a single or multiple stemmed shrub of 2-6-meter height [23-28] stems are grayish-green in color, smooth in texture (Figure 3).

Figure 3: *Calotropis procera* planted in SATIS site, Suez Canal University, Ismailia, Egypt.

Mature stems have a deeply fissured, cork-like bark that is light brown in color [13-21]. The leaves are simple, sub-sessile, opposite decussate, slightly thick or fleshy, oblong, obovate to nearly orbicular, short-pointed to blunt at the apex and have a clasping heart shaped base (Figure 4).

Figure 4: *Calotropis procera* flowers and leaves.

The leaf blades are light to dark green with nearly white veins, slightly leathery, and have a fine coat of soft hairs that rub-off. Leaves are pubescent when young and glabrous on both sides on maturity. They have a waxy appearance and contain a white milky sap [29,30]. Leaves are large up to 15 cm long and 10 cm broad, with no leaf stalk [31].

The flowers are regular, bisexual with a faint odor, they are borne in clusters of ovoid flower buds in the forks of the uppermost leaves each cluster contains 3-15 flowers. The clusters are surrounded by involucre of several small oblong, pointed scaly caduceous bracts. The main stalk of these flower clusters (i.e., peduncle) is 20-55 mm long, and each flower has a stalk (i.e., pedicel) about 15-25 mm long. Calyx and corolla are 5-lobed; sepals 7-8 mm long; ovate acute, hairy outside; while petals 2-3 cm wide, white with purple tips internally; fruit ovoid, inflated, 8-12 cm long [13]. Flowers have crown-like center [31,21].

The fruits are follicle (8-14 9 6-9 cm), sub-globose to obliquely ovoid. Its apex is rounded, green, spongy, and smooth—that split and invert when mature to release seeds [30,32]. Seeds are numerous (350-500 per fruit), flat, obovate, 6 9 5 mm, with silky white pappus of 3 cm or longer [23].

## Ecology

*Calotropis procera* is a soft-wooded, evergreen, perennial shrub that forms mono-specific stands without or with few associated weeds such as *Alhagi graecorum*, *Convolvulus arvensis*, *Solanum nigrum* and *Cynodon dactylon* [33]. It is highly resistant to drought, it thrives in soils ranging from alkaline to saline [30,33], it was found inhabiting waste rock dumps, tailings storage facility, and evaporation ponds [34], as well as, along roadsides, watercourses, river flats and coastal dunes, it is often prevalent in disturbed areas [13,35,23].

The plant is known generally to tolerate habitats with annual precipitation of 150–1,000 mm per year and temperature range of 20 – 30°C (CABI 2005), however in Egypt it survived on precipitation rate of only 4.7 mm per year and temperature as low as 13.4°C [36]. As a result, *Calotropis procera* was found to produce deep roots and root suckers, and rarely grows in shallow soils over unfractured rock [34].

According to Ibrahim (2013), the effect of water deficit, water logging and salinity stresses were applied on *C. procera* to study its resistance capacity, as a result, the plant have reduced photosynthetic pigments significantly through leaf shedding, while in contrast, the shoot/root ratio were remarkably increased, presumably leaf shedding could reduce organs that are no longer in use and increases photosynthetic efficiency per unit area of land [37], besides it minimizes water loss and transpiration during the dry season [38]. In the meantime, increasing root system ensures reaching water and nutrient in far depths beyond the dry surface. Furthermore, *C. procera* tend to form small size populations in highly saline soils, and consequently high levels of Na were found in its leaves to cope with saline soil [26], in addition, leaves were alternately arranged providing self-shading in sunny seasons. Under water logging stress, however, soil O<sub>2</sub> deprivation might have induced leaf shedding in *C. procera* due to hormonal disorder and limited energy [17,23].

Galal, et al. [39], have revealed that *C. procera* thrived well from mid-summer up until the cold season, well represented by high size variation, however, starting spring, the population size showed declined values, they also illustrated that the plant did not produce any seeds during the period from December to March, and that the population structure exhibited high stability under the stress of urban areas.

On the other hand, Farahat, et al. [18], found that *C. procera* has high plasticity in its morphological and reproductive traits, in which it had continuous flowering for 8 months, with a peak in April and May, that helped in reproductive success of the species, however, the flowering season declines in both very high and low temperatures. According to Sen&Chatterji [40], seeds couldn't neither germinate at elevated temperatures nor exhibit any dormancy, they even couldn't remain viable for long time, as it was proven by experiment that two-year-old seeds have lost viability. Eventually, Sen & Chatterji [39] mentioned that fruit set got enhanced during long hours of sunlight and warmer climate.

*Calotropis procera* primarily reproduces by seeds [14], the pollen of *C. procera* is green and somewhat sticky [41], it transfers through cross-pollination by insects, particularly by species such as the monarch butterfly (*Danaus plexippus*), which uses *C. procera* as a host plant for various stages of its life cycle [23]. In Egypt, *Xylocopa leucothorax* males (exclusively) are the main pollinators while a *Scoliid* wasp is a facultative one [42]. It may receive more visits form pollinators and because of possessing larger flowering stalks it may disperse its seeds more efficiently [43]. *Calotropis* seeds have a silky pappus that helps to spread by wind, animal, and may be transported on long distances in flood waters [13]. Additionally, it reproduces by vegetative propagation through half stumps, as well as through stem, root suckers and cuttings.

The biological features of *Calotropis procera* is considered common among invasive plants, such as fast growth and dissemination, high seed production efficiently dispersed by the wind, non-specialized pollination system and high tolerance to poor soils [44,45]. It has been declared as an invasive species in Australia where control strategies suggested to remove the tree mechanically with its deep tap root and lateral roots to prevent suckering, furthermore, extensive competition with tall weeds or brushes especially grass might be an efficient way to weaken *Calotropis* and prevent seed germination, meanwhile, chemical control is advisable for larger *Calotropis* colonies [13].

Studying the population dynamics and demography of *Calotropis procera* in Egypt proposed that it is an efficiently performed species and had many plastic phenological, morphological, and reproductive attributes that enable it to show stable persistence under urban habitats conditions, colonize, and invade new ecosystems

[26,36]. Meanwhile, Brazilian experimental studies have proved its ability to tolerate specific edaphic conditions and hence suggested that it has the potential to invade such habitats [46,47].

### Allelopathy of *Calotropis procera*

*Calotropis procera* has allelopathic properties including germination inhibition, plumule and radicle growth reduction. A study aimed to examine the allelopathic potential of *Calotropis* species on seed germination and seedling growth of *Acacia ehrenbergiana*, *Acacia gerrardii* and *Acacia tortilis* [48], according to their study, the aqueous leaf extracts of *Calotropis procera* (Aiton) inhibited the seed germination, reduced the seedlings growth, biomass yield and biomass allocation in *Acacia* species. Besides, different concentrations of *C. procera* leaf extract had an allelopathic effect on the seed germination of barley (*Hordeum vulgare* L.), wheat (*Triticum aestivum* L.), cucumber (*Cucumis sativus* L.), fenugreek (*Trigonella foenum-graecum* L.), Alssana (*Senna occidentalis* L.), tomato (*Lycopersicon esculentum* Mill.), and eggplant (*Solanum melongena* L.), showing that, the final germination percentage decreased with increasing leaf extract concentration [49,50]. In addition, Yasin, et al. [51] suggested that the delay in seed germination and the reduction in germination index might reflect the presence of water-soluble inhibitors in *C. procera* extract, they added that It has widespread and persistent occurrence near barley, oat, rice, sorghum, maize, cotton, sugarcane and especially wheat crop fields, which suggests some adverse effects on these crops through allelopathic interactions. Lastly, allelochemicals present in leaves and stems of *C. procera* strongly inhibited the germination, seedling growth, fresh and dry biomass of *Pennisetum americanum* (L.) Leeke and *Setaria italica* (L.) [52].

### Medicinal Importance

Members of the family Asclepiadaceae secrete milk-like latex that is known traditionally to heal wounds and stop bleeding of fresh cuts [21]. Therefore, Shivaprasad, et al. [53] have tested the scientific validity of this knowledge on four plant species to find that the latex exhibited significant abilities of both blood coagulation and thinning, meaning that the latex contains thrombin like enzymes responsible for clot formation and plasmin like action dissolving it.

Members of the family are also known for treating heart failure since they are rich in cardiac glycosides [8,9]. Cardiac glycosides are cardioactive compounds belonging

to triterpenoids class of compounds, helps in cases of heart failure by increasing heart contraction strength [54]. Moustafa, et al. [55] have studied the cardiac glycoside effect extracted from the aerial parts of *Calotropis procera* on several muscles, along with some flavonoids and saponins, they indicated a direct action of the extract on the myocardium, as it increased heart beats and heart contractions, moreover, the compound has increased the motility of smooth muscles as mentioned by Brian, et al. 1985 [53], and on the other hand it had a relaxing effect on the contracted skeletal muscles. Those effects were attributed to the glycosides actions on neural tissue which influence the mechanical and electrical activities of the heart improving vascular resistance [56]. Further studies on cardiac glycosides have also proven anticancer properties, in (2014), Ibrahim et al., have tested the methanolic extract of the root barks of *Calotropis procera* on lung and prostate cancer cell lines showing remarkable effects compared to the positive control Cisplatin. Besides, Nalini, et al. [57], have confirmed the anticancer properties of *Calotropis procera*, stating that it acts as an antiglioblastoma against LN-18 cancer cells, they declared that it has potential application and can be incorporated in developing anticancer drug.

Kazeem, et al. (2016) [58], have evaluated the antidiabetic characters of *C. procera* leaf extract, it revealed an inhibitory effect of carbohydrate hydrolyzing enzymes,  $\alpha$ -amylase and  $\alpha$ -glucosidase. Similarly, Abd-Alrheam & Shehri (2015)[59], have successfully used leaf extract as an antidiabetic agent on male albino rates, they also recorded significant decrease in levels of serum cholesterol and triglycerides, which probably an effect of saponin content that has potential effect in the treatment of hypercholesterolaemia by interfering with intestinal absorption of cholesterol [60].

On the other hand, *Calotropis procera* was found to be highly toxic when introduced to mice food, resulting in high abortion rates [61]. In addition, Ahmed, et al. [62], have assessed the toxic effect of latex and ethanolic leaf extract of *Calotropis procera*, on the heart and testis of male albino rats, proving high toxicity and recommending the use of *C. procera* as rodent control.

### *Calotropis procera* as Pesticide

Studies have determined that some botanical compounds such as alkaloids, nicotine, anabasin and lupitin in the extracts of *Calotropis procera* latex produced high mortality against mosquito larvae, which make it very efficient in the control of several mosquito species [63-65,10]. Additionally, the plant was discovered to be

highly toxic to the white garden terrestrial snail *Thepa pisana*, by the effect of uscharin that was extracted from the latex [7].

### ***Calotropis procera* as Renewable Energy Source**

Erdman & Erdman [11], suggested that hexane extraction of *Calotropis procera* could be used as a substitute for petroleum or petrochemical feedstocks, they claimed that *C. procera* yields high-density fluid, rich in hydrocarbon. In their study, the ratio of carbon and hydrogen in the extraction were similar to crude oil and the heat value content was comparable to crude oil, fuel oil and gasoline. Besides, Barbosa, et al. [12] have implied the high concentrations of seeds oil and fatty acids from *C. procera* in different localities in Brazil, they suggested that oil content and total biosynthesis of saturated fatty acids have been increasing with the increased temperature and drought, and finally concluded that *C. procera* has potential as biodiesel feedstock.

### **Molecular Studies**

Not too many molecular studies have dealt with *Calotropis procera*, in El-Bakry, et al. [66], have studied the genetic variation of *C. procera* in six different phytogeographic regions in Egypt, the study showed high polymorphism among the tested populations in which, Aswan population had the highest polymorphism of all and hence the most diverse gene pool, the six sampled localities where clustered into three distinct groups; Aswan, Feran valley and the remaining four localities, New Valley, Cairo-Suez road, Nuweibaa, and Arish, the study also revealed that highest similarity was between the populations of Cairo-Suez road and Nuweibaa, while Feran population exhibited the furthest distance.

El-Bakry, et al. [67], investigated the phytochemical polymorphism among *Calotropis procera* populations collected from the same six localities of the previous study, there was a significant difference in primary metabolites; carbohydrates and proteins, and secondary metabolites; cardiac glycosides and flavonoids, among different populations. The maximum values of carbohydrates and cardiac glycosides were recorded in the population from Wadi Feran, while the minimum values were recorded from Cairo-Suez road and New Valley. Meanwhile, proteins had its highest concentration in Aswan and the lowest from Arish. On the other hand, flavonoids attained their maximum concentration in Al-Arish and their minimum in Nuweibaa. El-Bakry et al. added that, proteins had decreased with the increase in soil chlorides, calcium, magnesium and potassium, while

flavonoids concentrations had increased directly with the increase of chlorides, sodium and potassium in soil.

Furthermore, three *Calotropis* genotypes from three locations; El Maghara, Shalateen and Saint Cathrine, were investigated using two molecular techniques; RAPD-PCR and ISSR, resulting in two cluster dendrogram, one included El Maghara and Shalateen genotypes, while the other was Saint Cathrine, which indicated high similarity between El Maghara and Shalateen populations and Saint Cathrine of least similarity [27].

### **Discussion and Interpretation**

Several studies have suggested the invasive potential of *Calotropis procera* which depends on the different traits it possess that shows fast growth rate, effective dispersion, high adaptation to wide range of environmental conditions or – quoting Ismail (1992)-“it has no Achilles heel”. However, the studies didn't detect any actual alteration of ecosystem or competition over space or resources with any other species so far. According to the previously mentioned studies, it was observed that *Calotropis procera* only exhibited invasive behavior in habitats where it was introduced into such as south and central America and Australia, those habitats were characterized by elevated rates of precipitations and high nutrient content in their soils in comparison to the Egyptian arid habitats where *C. procera* is originally a native plant. On top of that, seeds of *C. procera* can hardly germinate in extreme temperatures which is the case in Egypt's hot and cold seasons, however, Brazil and Australia have no such extremes meaning that seed germination can be successful all year round probably resulting in exponential increase in populations. To sum up, the invasion danger of *C. procera* is highly dependent on environmental conditions of different habitats, the extremely arid habitat in Egypt doesn't encourage the plant to grow widely as well as extreme temperature in both summer and winter inhibits seed germination for a period of time until conditions are suitable over again and hence limiting the growth and dispersal of the populations.

*Calotropis procera* populations in Egypt are highly polymorphic which indicates highly divers genetic pool that can hardly be threatened, furthermore, molecular studies suggested that there is a correlation between the edaphic conditions of a population and the nature of its metabolites since they differed in different soils [66]. Further study of this feature can be beneficial in

identifying which population to be targeted in medicinal industries and which in hydrocarbon synthesis.

Regardless to its allelopathic effect to some crops, *Calotropis procera* has several ecologic roles, its ability to accumulate several elements from different soils serves as natural phytoremediation [68-71], can possibly improve the quality of soil and hence rehabilitating abandoned and exhausted lands. In Egypt, there has been respective number of *C. procera* populations in intensive industrial regions such as Helwan south of Cairo [18,26] it's one of the most polluted areas in Egypt, consequently the presence of *C. procera* could act as a natural refiner for air and soil. As was mentioned by Lottermoser [14], *C. procera* had the ability to uptake high concentrations of Uranium in its tissues when grew in an abandoned mining site in Australia not to mention, vast number of heavy metals and natural elements were detected in its tissues that correlated highly to soil content. Another ecologic role, *Calotropis procera* is known to attract about 80 animal species, which range from casual visitors to those dependent on the plant for completing their life cycle [72], which provide highly productive ecosystem to abandoned lands. Furthermore, its appearance can be used as an indicator of overgrazing and poor soil and hence drive the attention to manage the stressed lands.

In an overpopulating developing country such as Egypt, having *C. procera* is a blessing, it is famous for its various medicinal and phytochemical properties along with hydrocarbon content that can be used as an alternative clean source of energy, it also can be used as a safe pesticide and rodent control without leaving harmful chemical traces. *Calotropis procera* presents such a rich natural resource that must be utilized industrially, it provides ecofriendly solutions to our pollution, energy limitation and habitat degradation problems.
