Abstract

Patients with systemic lupus erythematosus (SLE) have increased susceptibility to infection by Pneumocystis jerovecii but this condition has rarely been reported in Bangladesh. Pneumonias due to Pneumocystis jerovecii commonly occur in immunocompromised hosts. Although it is a treatable infection, it is associated with high motility. Patient with systemic lupus erythomatosus increased susceptibility to infection by Pneumocystis jerovecii. Here we describe a patient with SLE who developed Pneumocystis pneumonia (PCP). A 37-years old female was a known case of SLE for 12 years admitted in BSMMU with the complaints of fever & cough for 3 months and breathlessness for 1 month. The patient was treated with corticosteroids and cyclosporine within 2 months before presentation. Diagnosis was established based on the findings of induced sputum by Giemsa staining. This case demonstrated that PCP should be included in the differential diagnosis of patients of SLE presenting with pneumonic process.

Keywords: Pneumocystis jerovecii; Pneumocystis pneumonia (PCP); Systemic lupus erythomatosus (SLE)

Introduction

The occurrence of pneumocystis pneumonia in patient with collagen disease on immunosuppressive therapy is not uncommon. But only a few case reports are available about this infection in active untreated collagen disorders. The diagnosis of PCP is done either by induced or spontaneous sputum analysis, or by carrying out a bronchoalveolar lavage and transbronchial lung biopsy. Recently we encountered a case of PCP in SLE patient where definitive diagnosis based on the demonstration of Pneumocystis jerovecii obtained from induced sputum

Case Summary

A 37 years old female, non diabetic mother of one child hailing from Fenny was a known case of SLE for 12 years admitted in BSMMU with the complained of fever & cough...
She was evaluated for the cause of breathlessness. Urine & blood culture was sterile. Sputum examination did not show acid fast bacilli. Chest X-ray revealed bilateral diffuse infiltrate, more in perihilar regions. CT scan of chest showed bilateral diffuse infiltrate, more in perihilar regions, nodular densities. Echocardiography showed mild pericardial effusion, EF 67%, pulmonary arterial pressure 45mmHg. ECG showed normal findings. Laboratory report reveals Hb-11.2g/dl, WBC-9500/cumm with 93% neutrophil, 06% lymphocytes, and 1% monocytes, ESR-120mm in 1st hour and platelet count 3,00,000, Alanine aminotransferase 15U/L, S.creatinine 1.06 mg/dl. First sputum for pneumocystis jirovecii showed negative but induced sputum by 3%NaCl showed pneumocystis jirovecii by Giemsa stain done at Clinical Pathology Department of BSMMU (Figures 1A and 1B).

**Discussion**

Pulmonary manifestations of connective tissue diseases are a diagnostic challenge to the clinicians. It could be disease related due to immune mediate insult, vasculities, pulmonary hemorrhage, and pulmonary hypertension or caused by infection. Opportunistic infections with organism like pneumocystis jirovecii frequently complicate immunosuppressive status.

The mechanism of immune suppression in patients with SLE who have PCP is usually multi-factorial2, and may be related to underlying diseases, cytotoxic therapies, or malnutrition. However, the development of PCP in most patients with SLE is associated with daily administration of corticosteroids and with the development of lymphopenia3. Corticosteroids cause immunosuppression mainly by sequestration of CD4+T-lymphocytes in the reticuloendothelial system and by inhibiting the transcription of cytokines4-5. Corticosteroid therapy is a rare but possible independent predisposition to Pneumocystis jirovecii infection 6-7. Prolonged corticosteroid therapy is characterized by a significant immunological dysfunction.

In this case patient was treated by cyclosporin with prednisolone and she was also lymphopenic, may decrease CD4 count8. This impairs cellular immunity and predispose to opportunistic infection like pneumocystis jirovecii. The diagnosis of PCP was made by sputum analysis in our case. The sensitivity of the sputum analysis is 50-60%, though less sensitive9, sputum examination is highly specific for organism10.

**Conclusion**

Pneumocystis pneumonia is a fatal disease. Pneumocystis pneumonia occurs mostly immunocompromised patient. The patient response well to the anti pneumocystis treatment. The clinicians should be aware that, at some point of time immunosuppressed patients can present with concurrent infections with Pneumocystis jirovecii.
